

nevisCura Bed Sensor at inter pares Seniorenenzentrum Lentföhrden

Facility:

- 90 beds
- Alarm connection to Cereda nurse call system

Result:

- No resident with a bed sensor has fallen since
- This has resulted in fewer hospital stays and no more femoral neck fractures overall

Why should the bed sensor be used?

A system was needed, particularly for dementia care, that was easy to use, triggered alerts in a timely manner, and was less prone to breakdowns. The system was to be used primarily for residents with dementia, who often get up without thinking and have difficulty assessing their surroundings cognitively.

How does the bed sensor support everyday work?

As soon as a leg swings over the bed sensor, the alarm is triggered via the nurse call system. This has reduced the additional nursing workload. Processes have been optimized.

Advantages

- Significantly more robust than pressure mats
- Easy to use
- Quick alert, e.g., even if just one leg is over the edge of the bed
